Antigravity IDE & Autonomous Runtime Architecture

The Enterprise Pair-Programming & Multi-Agent Development Playbook

Executive Architecture Summary: A complete architectural blueprint for orchestrating Google DeepMind Antigravity, local PowerShell 7 runtimes, non-destructive execution guards, custom agent skills, and zero-latency pair programming on Windows 11 development machines.

1. The Autonomous Agentic Runtime Environment

Antigravity represents a fundamental evolution beyond autocomplete copilot models into proactive, autonomous pair-programming. Operating directly on the local filesystem, shell, and process tree, the agent acts as an autonomous engineer capable of running terminal commands, inspecting live DOM states, managing background daemons, and reading/modifying source code across multi-file repositories.

- Unified Execution Shell: Native PowerShell 7 (pwsh) configured with strict non-interactive flags and UTF-8 encoding.
- Scratch Sandboxes: Dedicated artifact and scratch directories mapped outside version-controlled working trees to prevent repository pollution.
- Self-Healing State Management: Continuous state persistence through structured transcript journals and background task supervision.
- Reactive Wakeup Signals: Decoupled asynchronous polling replaced with event-driven notifications upon task completion.

2. Workspace Bootstrapping & Safety Gate Doctrines

Deploying autonomous agents into enterprise codebases requires strict architectural guardrails. Unconstrained file mutations risk race conditions and accidental project state regression. Implement pre-action validation and transactional change reviews.

```
# PowerShell 7 Non-Interactive Workspace Bootstrap
$ErrorActionPreference = 'Stop'
$env:PAGER = 'cat'
$env:PYTHONUNBUFFERED = '1'
Write-Host '== Pinnacle AI Agent Runtime Initialized ==' -ForegroundColor Cyan

# Verify working directory boundary
$TargetWorkspace = "C:\Users\futur\gemini_workspace"
if ((Get-Location).Path -ne $TargetWorkspace) {
    Set-Location -Path $TargetWorkspace
}
Write-Host "Active Workspace Locked: $TargetWorkspace" -ForegroundColor Green
```

- Pre-Action Verification: Mandatory non-destructive analysis prior to filesystem modifications.
- Atomic Change Bundling: Group multi-file refactors into single transactional commits with rollbacks.
- Persistent Dual-Write Leads: Enforce automated retention to both leads.json and leads.csv on every pipeline extraction.

3. Custom Skills Architecture & Dynamic Extension

Antigravity utilizes on-demand skill modules (SKILL.md) located in ~/.gemini/config/skills/. Skills load dynamically based on intent, saving context window budget while providing deterministic execution playbooks for specialized workflows.

4. Production Best Practices & Observability

Maintain persistent auditability through structured log rolling, process supervision, and zero-leak credential hygiene. Never embed API secrets directly in codebase configurations; source environment variables from isolated vault storage.

- TokenBudget Optimization: Mask repetitive stdout logs and filter extraneous test outputs to preserve context.
- Subagent Swarm Coordination: Delegate isolated research and heavy builds to background subagents, returning concise digests.
- CleanDelivery Standards: All generated client deliverables, video renders, and exports delivered directly to Desktop.
